# PRINCIPLES OF OPERATION

The handic 0050 is a PLL (Phase Locked Loop) Synthesized VHF/UHF AM – FM Receiver, controlled by a CPU (Central Processing Unit) via the Keyboard.

The VHF Mid Band (68 ~ 88 MHz) and High Band (138 ~ 174 MHz) are received in 5 kHz increments. Aircraft Band (108 ~ 136 MHz) is step up for 25 kHz increments, and the UHF Band (380 ~ 470 MHz) for 12.5 kHz increments.

Receiving frequency range, frequency determination, scanning speed, delay time, etc., are all functions controlled by the CPU. The CPU is able to do only the assigned functions, and no modification of the CPU is feasible.

The following paragraphs explain the operation of the circuit in terms of the functional blocks:

A varactor (variable capacitance diode) tuning ("Automatic Tuning System") is employed on all Bands.

Field-effect transistors (FET) are used in the RF/MIX circuits of Mid, High and Aircraft Bands, to achieve optimum mix-modulation and mutual-modulation characteristics. Q118 amplifiers 10.7 MHz IF. A 10.7 MHz monolithic Crystal Filter is incorporated for better selectivity.

IC-101 contains Local Oscillator, Mixer, IF Amplifier, Quadrature FM Detector, Noise Amplifier and Detector. A Crystal Oscillator produces 10.245 MHz, which mixed with 10.7 MHz, resulting in 455 kHz IF. A 455 kHz Ceramic filter is provided to increase selectivity. The 455 kHz IF is amplified in the IF Amp stage, and a Quadrature FM Detector detects it to an audio signal. A portion of the 455 kHz Ceramic Filter output is picked up, amplified and detected by the AM IF Amp, which consists of Q120, 121 and D119, and then applied to the next stage via the ANL circuit.

Detected output of AM and FM is applied to IC-2. The IC-2 selects the AM or FM output, and also does Mute switching. The AM Pre-Amp consists of Q129 and Q130. IC-105 is an AF Power-Amp. Q127, 128 produce an approximately 2.5 kHz key peep tone with each valid key input.

Zeromatic circuit consists of IC-104 and Q126 and functions in search mode.

Noise Amp/Detector consists of Q119, IC-101 and D118, which converts the noise to proportional DC level to control audio mute and CPU via IC-103, D122, 123 circuit.

IC-1 is the CPU. The CPU does data processing, calculation, etc. Unstable supply voltage ( $V_{DD}$ ) to the CPU can produce CPU malfunctions, such as wrong data processing, wrong data transfer, etc. To overcome this, C23 and D35 'initialize' the CPU. Initialization is done when AC or DC power is supplied to AC plug or DC connector. Figure 1 shows initializing waveform.

Figure 2 shows the Clock waveform. Data outputs from CPU are level shifted in IC-2 and applied to PLL circuit which consists of IC-12, 13. Also the data outputs are converted from 4 lines to 16 lines in IC-3, 4 and then written in IC-5, 6.

The memory data are picked up as needed, and applied to CPU via IC-7 and IC-11, for calculation.

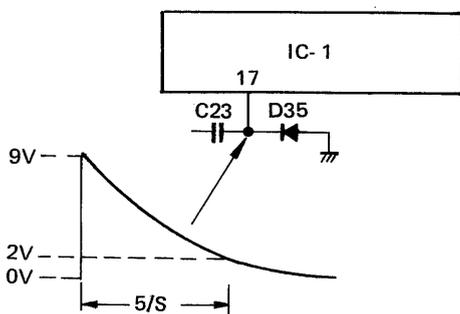

FIGURE 1

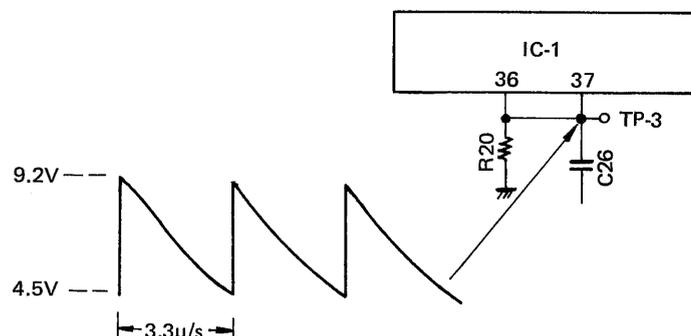

FIGURE 2

The CPU does the Clock count. IC-8, 9 pick up a 6.4 MHz Crystal oscillated frequency in the PLL, and produce 25 Hz to supply CPU with the 25 Hz. To protect Clock count from a momentary power failure, the Clock backup circuit consisting of Q135, 136, D137, 138 and a 9 volt Battery activates.

Output from PLL circuit controls the VCO via a Low-Pass Filter which consists of Q2, 3, 4 and D3, 4, 34.

All circuits except Audio Power Amp circuit are supplied with stabilized voltage. The CPU power supply is 9 volts from a DC – DC converter which works on well-regulated 5 volts. This is to prevent CPU malfunction due to low voltage, such as the sharp voltage drop when an engine starts when the unit used in a vehicle.

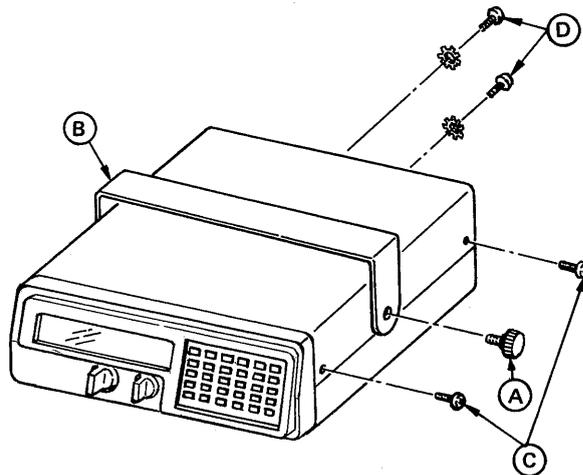

The handic 0050 draws approximately 220V – 60 mA AC, or 12V – 120 mA DC current to keep clock count even when the unit power switch is OFF.

Be sure to disconnect the AC plug (DC connector) when changing any component part for repair.

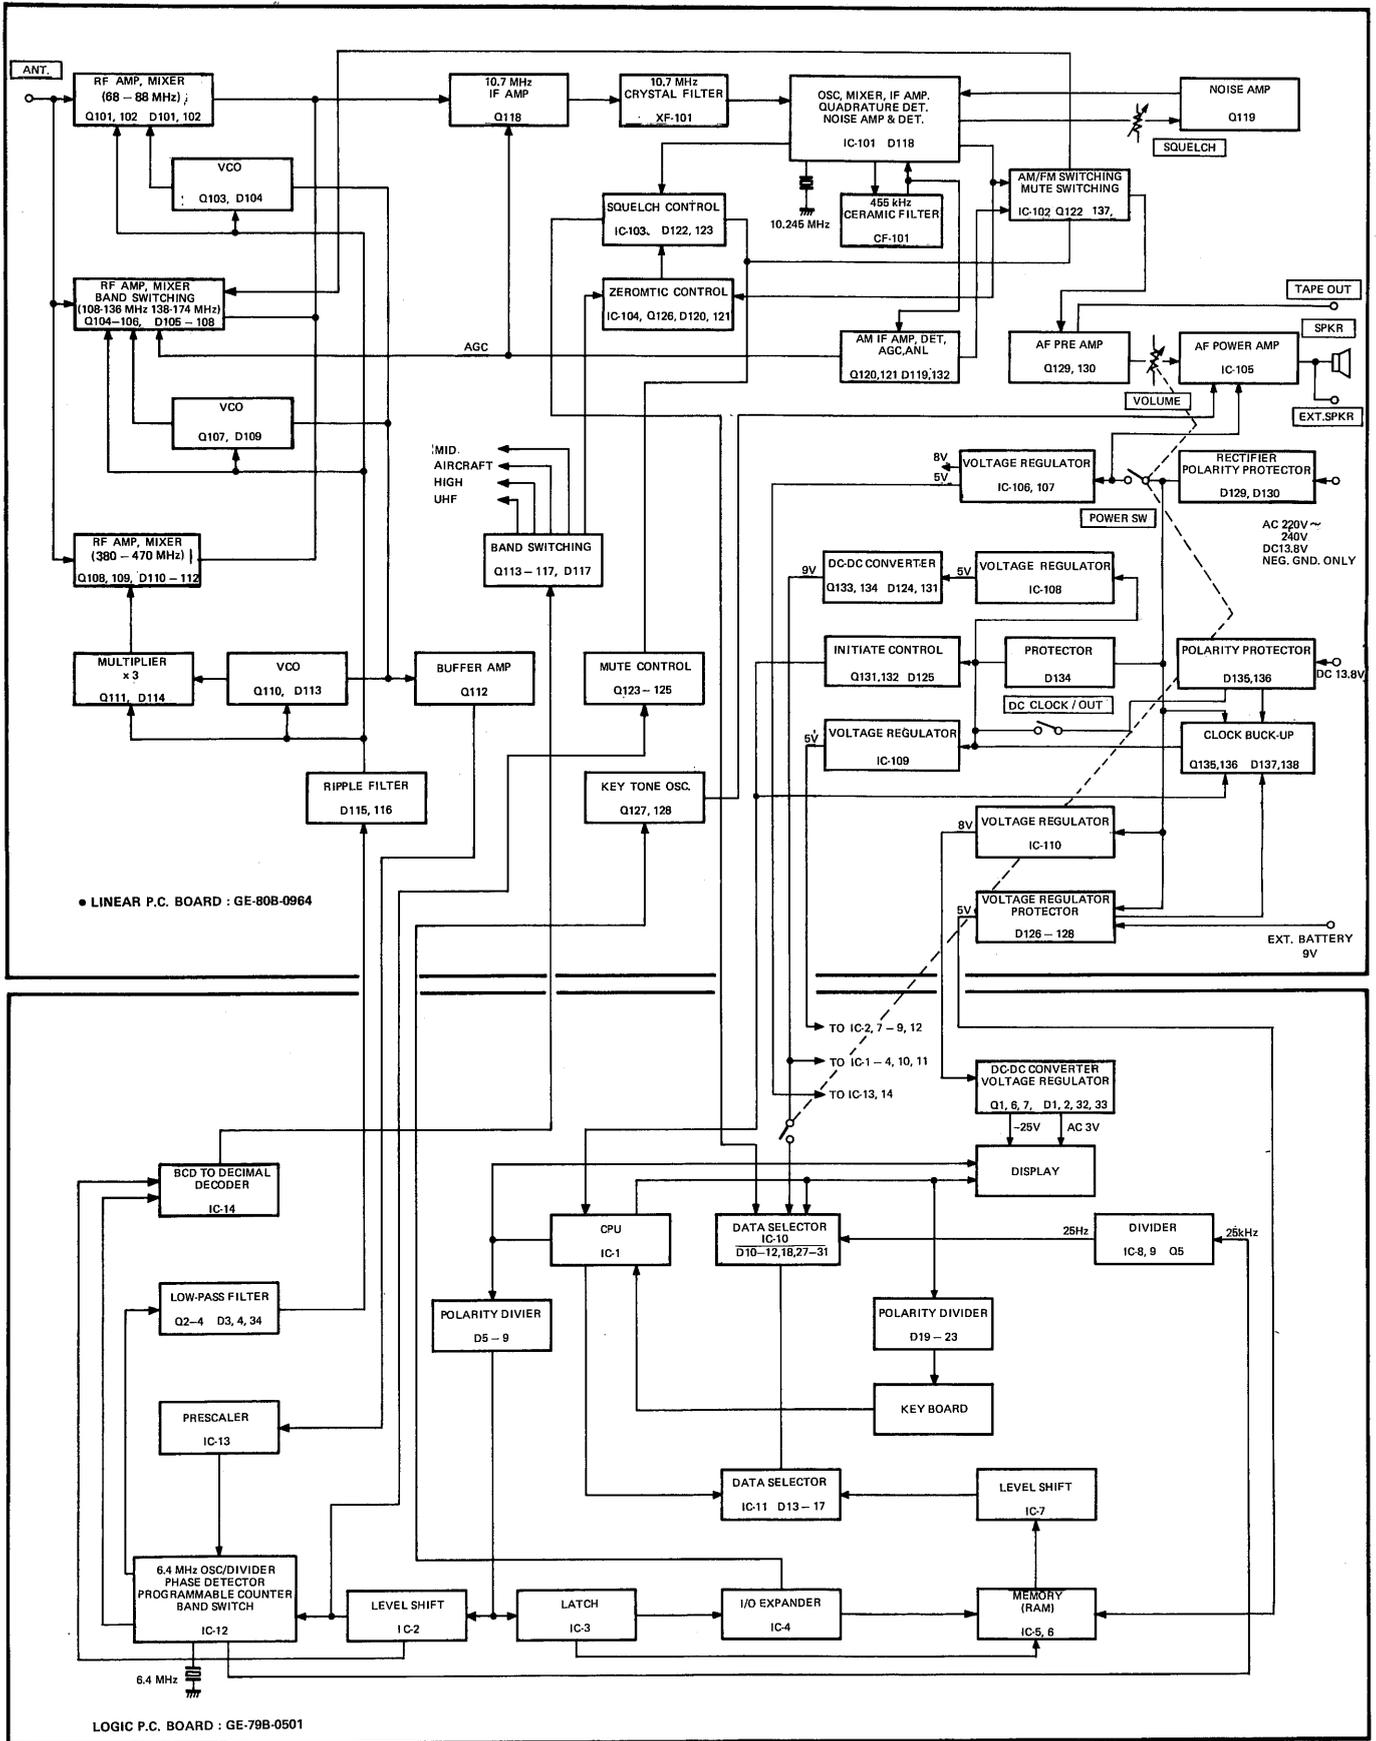

In the event of IC latch-up while checking the circuit, just disconnect the power source for about a minute.

# ALIGNMENT AND TEST POINT POSITIONS

## ALIGNMENT PREPARATION

### Test equipment required

1. Oscilloscope (0 ~ 500 kHz, 0 ~ 50 MHz)
2. AC VTVM
3. DC VTVM
4. Frequency Counter (60 MHz)
5. 8 ohms dummy load
6. Slow Sweep Generator with variable marker (10.7 MHz)
7. VHF Sweep Generator with variable marker (68 ~ 88 MHz, 108 ~ 174 MHz)
8. UHF Sweep Generator with variable marker (380 ~ 470 MHz)
9. FM Signal Generator (68 ~ 88 MHz, 138 ~ 174 MHz, 380 ~ 470 MHz)
10. AM Signal Generator (108 ~ 136 MHz)

**NOTE 1:** Use non-metallic tuning tools.

The test equipment and Receiver should be warmed up at least 10 minutes before proceeding with alignment. Input signal from the Generator should be kept as low as possible and still obtain usable output.

**NOTE 2:** A 9-volt battery is required to hold the memory when AC is disconnected. Always be sure the unit is loaded with a fresh 9-volt battery or the pre-programmed channels will be lost (and will have to be re-programmed).

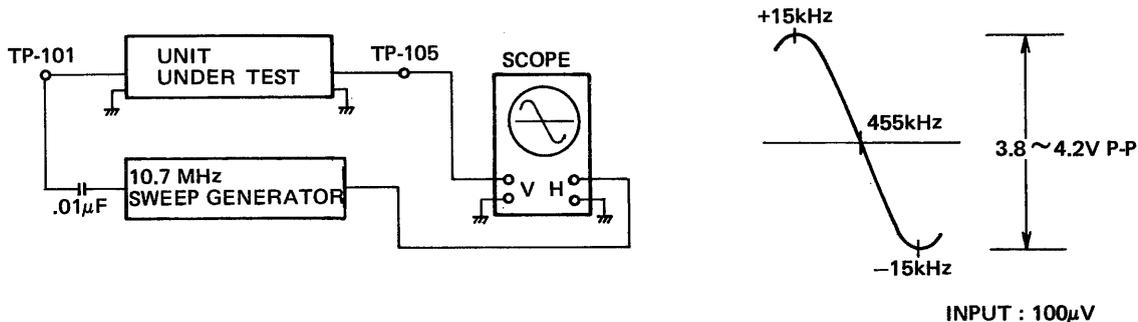

## REFERENCE FREQUENCY OSC ALIGNMENT

 Step 2: Adjust TC-1 so that the frequency is 6.40000 MHz  $\pm$  10 Hz.

**NOTE 1:** If 6.4 MHz fails to oscillate, it may be due to IC-12 latch-up.  
 Unplug the power connector momentary to turn power supply completely off.

## IF SECTION ALIGNMENT

- Step 1: Connect instruments as shown below.

- Step 2: Adjust T105 for maximum output so that the 455 kHz marker is in the center of the discriminator curve and for best linearity as shown above.

## ZEROMATIC FUNCTION AND HOW TO CHECK IT

\* Zeromatic functions when OUTPUT 1 is in "H" level.

$e_1$	$0 < e_1 < e_3$	$e_3 < e_1 < e_2$	$e_2 < e_1 < V_{CC}$
OUTPUT 1 (Pin No. 2)	L	H	L
OUTPUT 1 (Pin No. 4)	H	L	H

To adjust  $e_1$  voltage, receive signal in Manual mode, and set T105 to get half supply voltage (IC101, 4 pin). It is convenient to use National Weather Service Signal for the adjustment.

In the event Zeromatic does not function right, refer to "REFERENCE FREQUENCY OSC ALIGNMENT" and check 6.4 MHz, and adjust T105 again.

**NOTE:**

TP-2 is for checking PHASE Lock/Unlock Detection.

PLL circuit is locked: Low level

PLL circuit is unlocked: High level or Pulse output

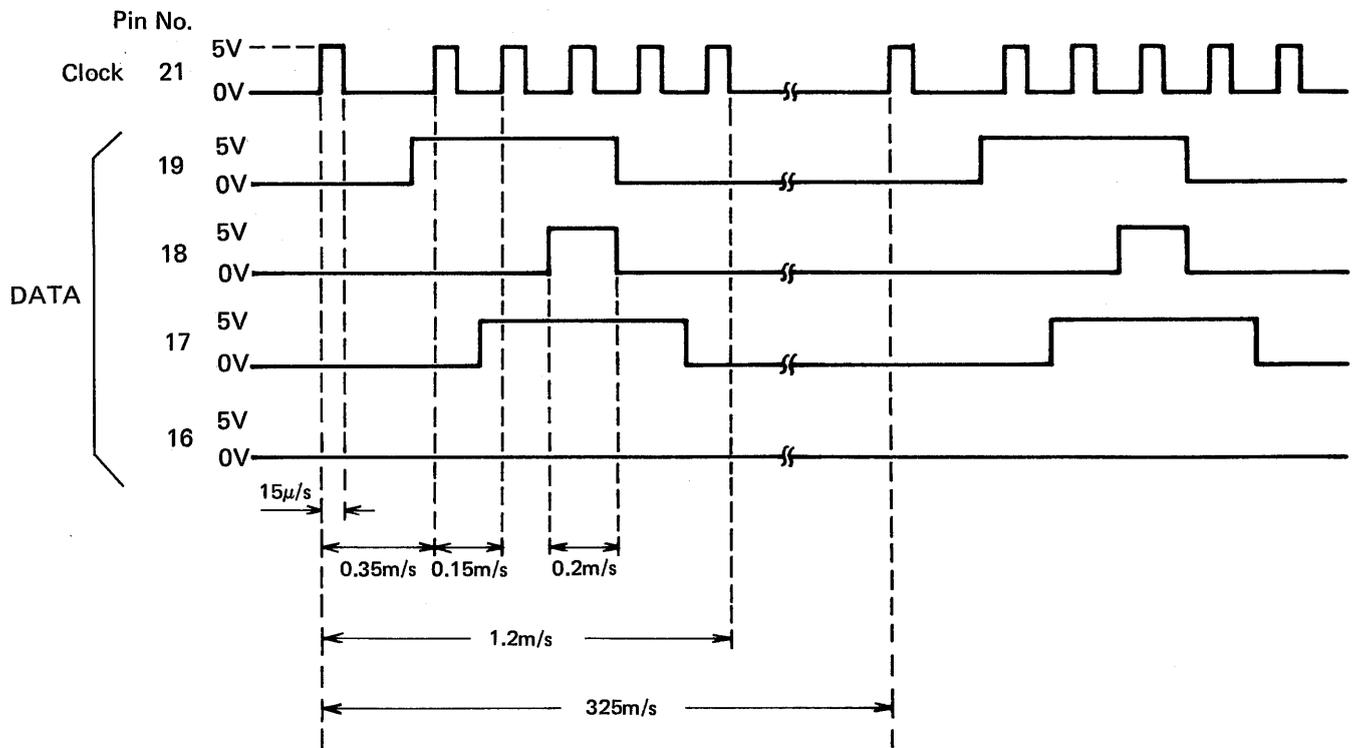

TP-3 is for checking CPU Clock Oscillation:

approximately 300 kHz. Observe 300 kHz sawtooth waveform with an oscilloscope.

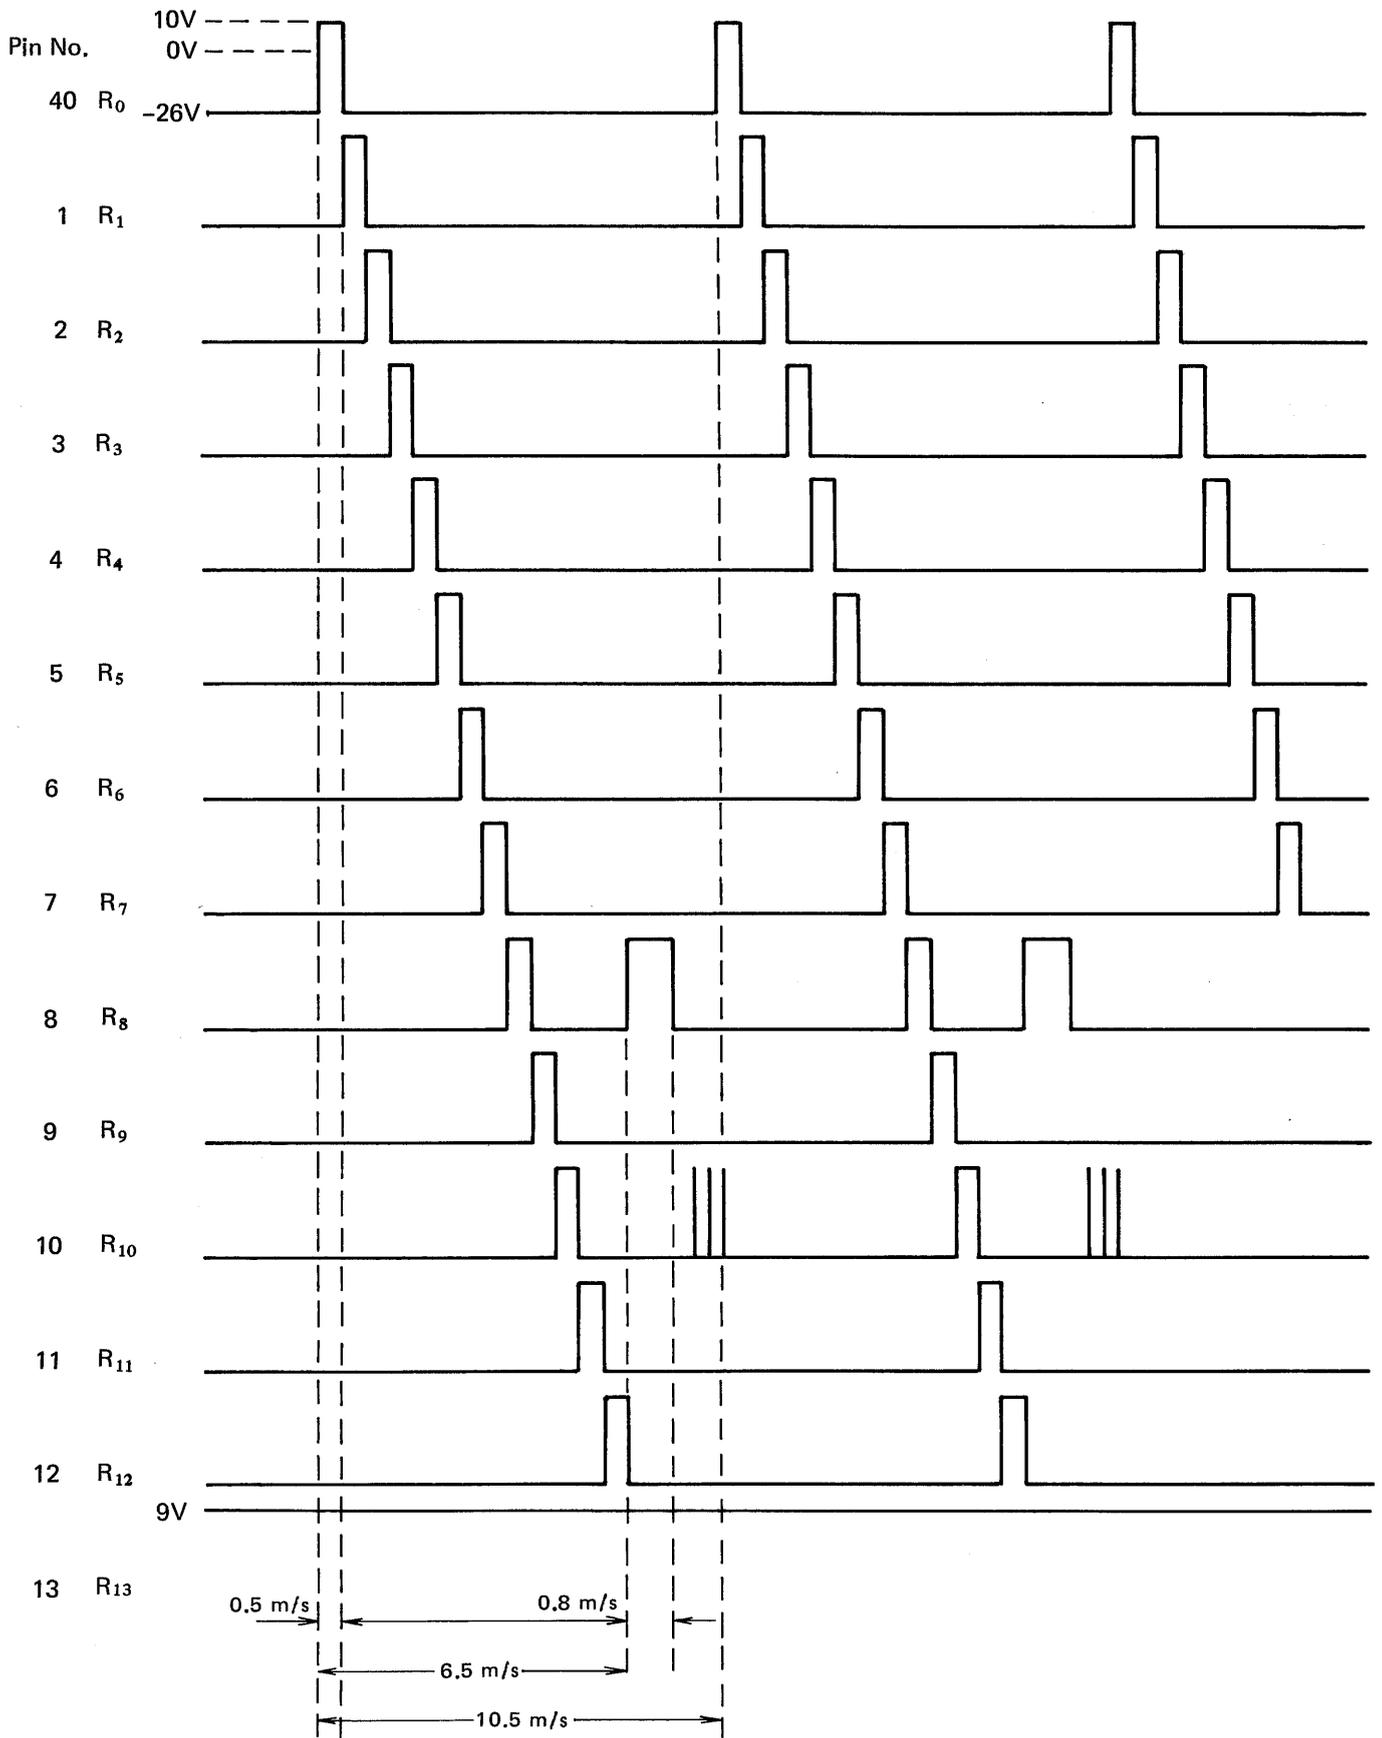

TP-106 is for checking AM Detector output.
