GENERAL

The TS-930S receiver is quadraple conversion and the transmitter is double conversion in the TUNE mode and triple conversion in the SSB, AM and FSK modes. Fig. 1 shows the frequency configuration of the receiver and Fig. 2 shows that of the transmitter.

Fig. 1 RX Frequency configuration

Fig. 2 TX Frequency configuration

VCOs (voltage controlled oscillators) in the Signal unit

There are three VCOs in the Signal unit X57-1000-11. Q16 operates at 45.03 to 54.42999 MHz, Q15 at 54.43 to 64.42999 MHz and Q14 at 64.43 to 74.9299 MHz, the first VCO is used for operation from 100 kHz to 9.49999 MHz, the second from 9.5 to 19.49999 MHz and the last from 19.5 to 29.99999 MHz.

• HET (heterodyne) generation in the Signal unit

Oscillator Q25 uses a 3rd overtone crystal to generate a 36.1 MHz heterodyne signal.

CAR 1 in the Signal unit

Q119 operates at 8.83MHz with crystal X5 for the CW, TUNE and AM modes; at 8.8315MHz with X3 for the USB mode; and at 8.8285MHz with X4 for the LSB and FSK modes. (CAR 1 frequency shifts to 8.82779MHz in the

FSK mode.) The CAR 1 oscillator is a VXO (variable crystal oscillator) which, together with the CAR 2 oscillator, forms the SSB-slope-tune and CW-VBT circuits.

CAR 2 in the Signal unit

Q75 is a VXO, operating at 8.375MHz.

• CAR 3 in the Signal unit

Q140 operates at 100kHz for the CW, TUNE and AM modes; at 101.5kHz for the USB mode; and at 98.5kHz for the LSB mode. This output is fed to the 2nd CAR mixer Q80 and to Q152 as signal CAR in the SSB, TUNE and FSK modes and as the carrier in the CW mode.

• CAR 4 in the Signal unit

Q158 operates at 99.2 kHz and is used for both demodulating CW signals and generating the CW side tone.

TS-930S

CIRCUIT DESCRIPTION

RX SECTION

The signal from the antenna is applied to the Signal unit X57-1000-11 RAT terminal, then applied to a low pass filter or one of 8 band pass filters through a 10dB or 20dB RF attenuator. The filters are selected according to BAND data (RB0 - RB3) output from the Digital unit X54-1670-00. Frequencies of these filters are shown in Table 1. The signal is then passed through the RF AGC circuit consisting of PIN diodes D34 and D35 (BA379) and is fed to the RF unit X44-1490-00 via the RRF terminal. In the RF unit, the signal is amplified by a matched pair of 2SK125s (Q1 a & b) and mixed with the VCO signal by the first RX mixer, another pair of 2SK125s (Q2), to obtain the 44.93MHz first IF signal. This is buffered by amplifiers Q3 and Q4 and fed back to the Signal unit via the RIF terminal. In the Signal unit, the 1st IF signal is filtered by an MCF (monolythic crystal filter), which has a bandwidth of approximately 10kHz, and is then applied to the 2nd RX balanced mixer. There, it is mixed with the 36.1 MHz HET signal to obtain the 8.83MHz 2nd IF signal.

The 2nd IF signal is applied to both the noise blanker circuit and the noise blanking gate (diodes D82, D84, D85 and D86). The signal, passing through the noise blanking gate, is then applied to filter XF1. (The standard XF1 is a 3kHz SSB filter; optional 500Hz CW (XF2) and 6kHz AM (XF3) filters are also available.) The filtered SSB signal is then mixed with the 8.8375MHz CAR 2 signal by the 3rd RX balanced mixer, Q65 and Q66 (3\$K73s), to obtain the 455kHz 3rd IF signal. The 3rd IF signal is amplified approximately 30dB by IF amplifier Q67, then filtered by a ceramic filter. (CF1, 3kHz and CF2, 6kHz filters are built in, and optional 500 Hz or 250 Hz XF4 CW filters are also available.) The signal is then amplified 30dB by Q128 and mixed with a 355kHz signal by the 4th RX mixer Q129 to obtain the 100 kHz 4th IF signal. This signal passes the notch circuit, and is IF amplified by Q130, and detected by either the SSB and CW detector D238 - 241, or the AM detector, depending on the mode. The detected audio signal is amplified by the 2-stage AF amplifier Q159, 160, then power amplified by IC3 to drive the speaker.

Table 1 RX BPF frequency

TX SECTION

The microphone signal is applied to the microphone input terminal MCL (for 500Ω microphones). Terminal MCH is provided for $50 k\Omega$ microphone and is selected by moving the connector. The MIC amplifier, consisting of Q146 and Q147, amplifies the signal by approximately 34dB when the MCL terminal is used. The amplifier gain is about 14dB when the MCH terminal is used. The amplified signal is applied to the MIC gain control, then applied to amplifiers Q82 and Q83 via terminal MV2. After being amplified by Q82 and Q83, the signal is applied to balanced modulator D140 (ND487C1-3R, a Schottky diode package) where a 455kHz DSB signal is obtained. The 455kHz DSB signal is buffer amplified by Q87 and is converted to a 455kHz SSB signal by CF1. This signal is applied to the RF speech processor consisting of Q71, IC6 and Q70 through buffer amplifier Q72. The processor output signal is applied to the 1st TX mixer, Q68 and Q69. When the processor is off, it is bypassed, and the signal continues through diodes D118 and D114. The 455kHz SSB signal is mixed with the 8.375MHz CAR 2 signal by the 1st TX mixer to obtain an 8.83MHz signal, which is then applied to filter XF1, where the unwanted side band introduced by the speech processor is removed. The signal is then amplified by IF amplifier Q57. ALC signal is applied to the 2nd gate of Q57. In the CW and TUNE modes, the 8.83MHz CAR 1 signal is fed directly to IF amplifier Q57 through buffer amplifiers Q121 and Q123, amplifier Q59 and switching diode D78. Full breakin is possible in these modes because the transmission signal does not pass through the narrow band filter. The signal output by Q57 is applied to the monitor circuit through buffer amplifier Q58. The signal is also applied to the TX 2nd mixer Q55 and Q56, where it is mixed with the 36.1 MHz HET signal to obtain the 44.93MHz signal. The converted signal is then mixed with the VCO signal by the TX 3rd mixer Q42 and Q43, to obtain the operating frequency.

It is then amplified approximately 22dB by wide band amplifiers Q41, Q40 and Q43, after unwanted signal components are removed by one of the TX band pass filters. The amplified signal is output from the DRV terminal and fed to the Final unit X56-1430-00. The drive signal line to the Final unit is automatically disconnected when a cable is connected to the transverter connector on the rear panel.

In the Final unit, the signal is amplified approximately 40dB by a three-stage wide band amplifier consisting of pre-driver Q1 (2SC2075), a push-pull driver (Q2 and Q3; MRF485s) and a push-pull final amplifier (Q4 and Q5; MRF422s). The amplified signal is then applied to the antenna through the Filter unit X51-1280-00, (optional) AT (antenna tuner) unit X57-1010-00 and Switch unit X41-1410-00. There are two models of the TS-930S: one with and one without the AT unit. The final amplifier uses

Motorola transistors, having an excellent IMD (intermodulation distortion) characteristic, a maximum collector dissapation (PC) of 290W and high reliability. 28V DC is applied to each transistor. The bias circuits for the predriver and driver are regulated by varistors and a transistor. The bias circuit for the final transistors is regulated by IC1 and Q7, and the diode characteristic between the base and emitter of the transistor is used to provide temperature compensation and is controlled by the heat sink temperature in proximity to the final transistors.

PLL CIRCUIT

The TS-930S uses a 10 Hz step digital VFO to control the operating frequency. Fig. 3 shows a block diagram of the PLL unit X50-1880-00. The PLL circuit uses three separate PLL loops (PLL-1, PLL-2 and PLL-3) to vary the operating frequency from 100 kHz to 30 MHz.

PLL-3 consists of IC13 and its peripheral circuitry. VCO-3 (Q29) operates within the 20 to 21.99 MHz range. IC13 incorporates a divider and phase detector, and divides (by 1024) the 10.24 MHz signal generated by X2 to obtain the 10 kHz reference signal. The signal output by VCO-3 is applied to IC13 pin 9 through amplifier Q28 and is divided (by a value ranging from 2000 to 2199) to obtain 10 kHz.

The phase of this 10 kHz signal is compared with that of the 10 kHz reference signal to lock VCO-3. The locked VCO-3 signal is applied to IC9 pin 14 through buffer Q33. The signal is divided by 1000 in IC9, IC10 and IC11 to obtain a signal which varies in 10 Hz steps in the 20 to 21.99 kHz range. The frequency division data for IC13 is delivered serially from the microprocessor in the Digital unit X54-1670-00.

PLL-2 consists of IC15 and its peripheral circuitry, VCO-2 (Q25) operates in the 49.8 to 54.78MHz range. The 20MHz signal generated by Q36 is applied to IC15 pin 19 through buffer Q34. This signal is divided by 1000 by IC15 to obtain the 20kHz reference signal. The VCO-2 signal is applied to IC14 (MIX 6) pin 2 through buffer Q26, where it is mixed with the 40MHz signal obtained by doubling the 20MHz signal from Q34 so that an output varying from 9.8 to 14.78MHz is obtained. This signal is applied to IC15 pin 10 through amplifier Q21 and is divided by a value ranging form 490 to 739 to obtain the 20kHz signal. The phase of this 20kHz signal is compared with that of the 20kHz reference signal to lock VCO-2. The VCO-2 output signal is applied to IC8 pin 2 through buffer Q27 and divided by 10 to obtain a signal which varies in 2kHz steps in the 4.98 to 5.478MHz range. The frequency division data for IC15 is also delivered serially from the microprocessor in the Digital unit. The 4.98 to 5.478MHz signal output from IC8 pin 5 is applied to IC6 (MIX 4) pin 2.

Fig. 3 PLL Block diagram and Digital control system

TS-930S

CIRCUIT DESCRIPTION

The 20 to 21.99 kHz signal from IC11 pin 12 is mixed with the 8.83MHz CAR 1 signal to obtain the 8.85 to 8.85199 MHz signal. This signal is applied to IC5 pin 5 through MCF1, MCF2 and buffer Q20, where it is mixed with the 4.98-5.478MHz signal from PLL-2, the resultant signal varies from 13.83 to 14.32999MHz in 10Hz steps. This is applied to IC4 (MIX 3) through buffer Q17 and is mixed with the 36.1MHz HET signal to obtain a signal which varies from 49.93 to 50.42999MHz in 10Hz steps. After being buffered by Q16, the signal is applied directly to IC3 (MIX 1) pin 5 when the operating frequency is between 9.5 and 19.49999MHz. When the operating frequency is between 100kHz and 9.49999MHz, or between 19.5 and 29.99999MHz, the output signal from Q16 is applied to IC5 (MIX 2) pin 2 through switching diode D15 and is mixed with a 10MHz signal, obtained by dividing the 20MHz signal by 2. The resulting 59.93 to 60.42999MHz signal is applied to IC3 through buffer Q15. Diode switching control, is applied according to the operating frequency by the Digital unit microprocessor.

In IC3, the above signal is mixed with the VCO signal, which varies from 45.03 to 74.92999 MHz, so that an output varying from 4.5 MHz to 15 MHz is obtained. This is applied to IC2 (divider) pin 2 through Q13 and Q12, and is divided by a value ranging from 9 to 30 to obtain a 500 kHz signal. This 500 kHz signal is applied to IC1 (phase detector) pin 7. The 500 kHz from IC19 pin12 is applied to IC1 pin 8 through Q4. The phases of these 500 kHz signals are compared by IC1. The comparator output signal is passed through an active filter consisting of Q1, Q2 and Q3, then sent to the primary VCO in the Signal unit through the FCV terminal as the VCO control voltage, so the VCO in the Signal unit is locked within the 45.03 to 74.92999 MHz range, in 10 Hz steps.

The 100kHz marker signal is obtained by dividing the 20 MHz signal by 200 by IC16 (÷ 10), IC7 (÷ 2) and IC19 (÷ 10). When the MARKER switch (CAL SW) is OFF, D20 is turned off to stop input to IC19 (1/10 divider) and Q40 is also turned off.

The FSK modulation signal is generated as follows: The 1 MHz signal obtained by dividing the 20 MHz signal is output from IC17 pin 9. This is divided by 218 or 235 by IC18, then divided by 2 by IC17. The FSK modulation signal which results is output from IC17 pin 13. When the KFS terminal is open, the level at the collector of Q38 is H and the level at the collector of Q37 is L. At this time, the frequency division ratio is set to 1/218 so that a 2.2936 kHz space signal is obtained. When the KFS terminal is closed, the levels at the collectors of Q38 and Q37 are reversed and the frequency division ratio is set to 1/235 so that a 2.1277 kHz mark signal is obtained.

Table 2 PLL data

DIGITAL CIRCUIT

Fig. 3 shows a block diagram of the Digital unit, which consists of 31 ICs including a custom CPU, µPD8049C-211 (IC6). The CPU uses a mapped I/O system on a common bus to control many signals. I/O signals are latched by IC25-29 to prevent noise from affecting other circuits. There are two encoder input ports; one for the main tuning control signal and the other for the RIT control signal. Each encoded input is applied to a logic circuit that determines both direction of rotation also sends information to the CPU to indicate the desired frequency change. The output of IC16 pin 3 or 4 determines the direction of rotation of the Main encoder. For example, when the encoder is rotated, the output at pin 4 goes to +5V. This output level is maintained until rotation is stopped. The output then returns to OV. If the dial is turned in the opposite direction, the output drops to -5V and is maintained until rotation is again stopped. Internal variations in IC16 itself determine which pin (3 or 4) must be connected for proper action of the main tuning dial.

The RIT rotary encoder operation is similar, but the output of IC19 pin 3 will always be as in Fig. 4, above.

Desired frequency change is sent to the CPU via D13, 14 for the Main encoder and via D18, 19 for the RIT encoder. This output data is in the form of data pulses and is at a rate of 4 pulses per encoder disk opening. For example, If the Main encoder is rotated so 10 slots are sensed, 40 pulses will be sent to the CPU. Tuning rate is 10 kHz per revolution in 10Hz steps. When the rotational speed of the main tuning knob exceeds 5–6 rev/sec, the step size is automatically increased in geometric progression. In other words the faster the knob is rotated, the greater the step becomes. The RIT control covers ±9.99 kHz.

IC13 (μ PD5101LC) is a C-MOS RAM which stores frequency data for the 8 memory channels, and VFOs A and B. IC13 back-up power is supplied by three 1.5V AA batteries, through diode D10, when the power switch is OFF. Since the required back-up current is only 10μ A, memories will be maintained for approximately 24hr, even if no batteries are installed, by the discharge current of C21. Power is supplied to IC13 through Q23 and Q24 when the power switch is ON.

IC1 through IC4 are display drivers. Display date is multiplexed from the microprocessor. Connectors 13 through 16 output to the display tube. Terminals a through g and DP are 7 segment and decimal point data for the display. Terminals P1 through P10 are signals for the analog-type display, which approximates a conventional dial pointer. Terminals G1 through G10 are display tube grid signals. Heater voltage at approximately 7 Vpp is generated by DC-DC converter Q14 and Q15 and is supplied to the display tube terminals FH and FG. Q16 is a switching transistor used to blank the display tube if the PLL unlocks. IC21 through IC24 are multiplexers. Whenever the collector of Q25 is "L" low, data from the inputs of IC21-24 (pins D0-D6) is distributed to the appropriate IC. Input data selection is by means of control signal from IC12 the address latch (pins Q1, Q2 and Q3). If the collector of Q25 is held "H" no data transfer can occur.

IC11 and IC12 form an 8-bit address latch and IC25 through IC29 are output data latches: IC25 and IC26 latch 8-bit frequency division data which is sent to the PLL unit (PLL-1) through terminals PL0 through PL7. IC27 and part of IC28 latch the band data which is sent to the Antenna Tuner through terminals AT0 through AT4. The remainder of IC28 latches the band data which is sent to the Low Pass Filter unit through LP0 through LP2. IC29 latches the band data sent to the RX BPF in the Signal unit through terminals RB0 through RB3.

By two gates of IC7, Serial frequency division data is output-gated and is sent to PLL-2 and PLL-3 in the PLL unit via terminals PLL2 and PLL1.

Q20, Q21 and Q22 form a reset circuit. If the voltage at the 5V line accidentally drops, Q21 is turned on and its collector level becomes "H". This turns Q22 on and a "L" pulse is generated at its collector. This pulse signal is applied to the CE terminal IC13 pin 17 to disable readwrite functions so that its contents are protected. Simultaneously, Q20 base becomes "H" and Q20 turns on. Therefore the logic "L" at Q20 collector is felt at IC6 pin 4 and the CPU is reset.

Tables 3 through 5 and Fig. 5 show various data input to and output from the Digital unit.

Table 5 Functions of μPD8049C-211 (Digital unit IC6)

ACCESSORY CIRCUITS

Noise blanker in the Signal unit

Fig. 6, 7 shows the noise blanker. The noise blanker consists of two circuits, NB1 and NB2. Noise sampled from the RX 2nd mixer (Q62 and Q63) output transformer is amplified approximately 70dB by Q28 to Q30 and Q32. The amplified noise signal is applied to both NB1 and NB2 circuits. In NB1, the noise is buffered by Q33 and detected by D52 and D53. The detector output is applied to switching transistor Q35. In NB2, the noise is applied directly to the noise detector circuit consisting of D54 to D56 and Q36. NB1 detects pulse noise included in the input signal and switches the noise blanking gate consisting of D82 and D84 to D86, which is located before the RX 2nd IF filter, XF1. The NB1 system is a conventional noise blanker. Noise detected by D54 to D56 and Q36 is shaped by IC2 so that only high level pulse noise components are extracted in the form of a square wave. This square wave is applied to both the switching transistor Q38, to control the 3rd RX mixer (Q65 and Q66), and to the NB gate through D57 and Q31 to switch the gate. The NB2 system is effective against radar-type pulse noise, commonly called "the woodpecker". The noise blankers are also used to reduce clicks generated by the digital VFO step reset pulse.

Fig. 6 Noise blanker circuit

Fig. 7 NB2 circuit

Fig. 8 NB2 timing chart

Speech processor in the Signal unit

A block diagram of the speech processor is shown in Fig. 9. An SSB signal, having passed 455kHz filter CF1 and buffer Q72, is amplified by Q71 and applied both to the detector consisting of D116 and D117, and to limiting amplifier IC6. The detected signal is applied to DC amplifiers Q73 and Q74, where it is logarithmicly compressed, and is then applied to the multi-meter to indicate compression level. The output level of IC6 is constant regardless of input level.

The output signal is applied to gain control amplifier Q70, then input to the TX 1st mixer. When the processor is off, it is bypassed through switching diodes D118 and D114. In the FSK mode, the signal is automatically compressed approximately 10dB (even if the processor switch is off) to equalize any variations in level between mark and space signals. In the FSK mode, the transmission power and ALC are adjusted with the PROC-OUT control.

Fig. 9 Speech processor block diagram

• Monitor circuit in the Signal unit

The SSB signal is sampled from the drain of TX 2nd IF amplifier Q57, is amplified by Q58 and Q125, and then applied to the product detector Q126. The detected AF signal is amplified by Q127, and applied to AF power. amplifier IC3.

Side tone circuit in the Signal unit

The 100kHz CAR 3 signal and 99.2kHz CAR 4 signal are applied to the product detector D238 to D241 to obtain an 800Hz signal. This 800Hz signal is applied to AF power amplifier IC3. Q152 is switched on by the STK line through D233, and side tone is generated when the key is closed. This side tone circuit makes it possible to vary the incoming CW pitch. Signals can be zero-beat by making the side tone pitch the same as that of the CW signal being received.

SWR calculation circuit in the Signal unit

Conventional SWR indicators require sensitivity adjustment for the forward wave level. The SWR metering circuit incorporated in the TS-930S makes this adjustment automatically. This new SWR calculation circuit is shown in Fig. 10. Forward wave voltage VSF and reflected wave voltage VSR sampled from the Filter unit are applied to the analog calculation circuit in the Signal unit. IC4 is a V-I converter for the (optional) AT-930 auto antenna tuner. Output from IC4 pin 1, proportional to VSR/VSF, drives the SWR meter. IC4 also includes an integrator, IC5 is a voltage comparator, and a triangular wave generator and Q53 and Q54 are switching transistors.

Fig. 10 SWR meter circuit

The VSF voltage is compared with a 0.5V REF voltage on IC4 pin 12. If VSF decreases (i.e. SWR increases) the voltage level at pin 14 increases. The output of IC5 pin 1 is a triangular reference signal and is mixed with the voltage from IC4 pin 14. Changes in the output of IC4 pin 14 affect the reference level of this triangular wave. IC5 computes the change and sends a square wave signal, whose pulse width and spacing are proportional to the change, to control conduction of switching transistors Q53, Q54.

See Fig. 11.

The voltage at IC4 pin 1 is a level proportional to VSR/ VSF, and is used to drive the SWR meter and also for AT-930 control purposes. VR16 ia an SWR meter adjust for initial setup only.

Fig. 11 Automatic SWR computing circuit waveforms

CW-VBT (variable bandwidth tuning) and SSB-slopetune in the Signal unit

Fig. 12 shows the CW-VBT and SSB-slope-tune circuits. The principle of CW-VBT operation will be explained first. When CAR 1 and CAR 2 are at their normal frequencies, the overall IF response is indicated by "A". When the CAR 1 frequency is shifted by Δ f1, the overall IF response curve shifts to that at "B". The circuit is designed so the CAR 1 signal lowers the VCO frequency fL by Δ f1. In this case, the IF bandwidth is fully opened, or normal. Whe the CAR 2 frequency is lowered by Δ f2, the 3rd IF filter frequency response curve shifts to that indicated by "C". Thus, the overall IF bandwidth is narrowed. The TS-930S VBT function is designed to operate as : Δ f2 = 2Δ f1. The overall IF bandwidth is narrowed by varying the CAR 1 and CAR 2 frequencies without shifting the overall IF response center frequency.

Next, the SSB-slope-tune function will be explained. When the circuit is designed so that variations in the CAR 1 and CAR 2 frequencies have the relationship $\Delta f1 = \Delta f2$, only the lower frequency (at the left limit of the overall IF reaponse curve, shown in Fig. 13) can be shifted by varying these frequencies. The higher frequency (at the right limit) can be shifted by varying just the CAR 2 frequency. In the TS-930S, these two operations are performed by separate controls. The CAR 1 frequency control voltage VF1 and CAR 2 control voltage VF2 are supplied from the Switch unit.

Fig. 12-A RX configuration Normal (wide) response

relationship

TS-930S

CIRCUIT DESCRIPTION

• Notch filter in the Signal unit

The notch filter is a bridged-T filter consisting of L, C and R components. It is located between the 4th RX mixer and the 100kHz IF amplifier Q130. The filter resonant frequency is shifted by varying the voltage applied to the cathode of vari-cap diode D217. The filter operates in all modes.

• AF-tune in the Signal unit

The AF-tune circuit is three-pole active filter built around IC7, located between the SSB/CW detector and AF amplifier Q160. AF-tune is available only in the CW mode. The tuning range is 800 Hz ± 400 Hz, or greater. When the AF-tune circuit is switched off, the circuit is bypassed through D248.

VOX and ANTI-VOX circuits in the Signal unit

Fig. 14 shows the VOX and ANTI-VOX circuits. The signal output by MIC preamplifier Q146 is applied to VOX amplifier Q145 through the VOX gain control. The AF output, sampled from the speaker line, is applied to the ANTI-VOX amplifiers Q149 and Q148. An adjustable DC bias voltage is applied to the base of Q148 to control the ANTI-VOX operating level. The digital signals output from these amplifiers are applied to the RS flip-flop IC10. The signal which is first input to the flip-flop has priority. Output from the flip-flop is applied to one-shot multi-vibrator IC9, and its output is applied to time constant circuit C449 and R567, which determines the VOX delay. This circuit configuration affords fast VOX rise time, and prevents VOX "chatter".

Fig. 14 VOX, ANTI-VOX circuit configuration

• Final cooling fan control circuit in the Filter unit

The final heat sink temperature is detected through thermistor TH1 on the Final unit. When the temperature reaches approximately 50 °C, a Schmitt circuit, consisting of Q16 and Q17, operates to turn Q22 on. Then, approximately 10V is supplied to the fan motor through the MOT terminal, as Zener D12 is cut off by D10 and Q19. This Schmitt circuit is designed to shut off when the temperature drops to about 45 °C.

• Temperature protection circuit in the Filter unit

This circuit also uses the signal from thermistor TH1 on the Final unit. When the final heat sink temperature reaches approximately $75-80\,^{\circ}\text{C}$, another Schmitt circuit, consisting of Q18 and Q19, operates. The collector of Q19 goes H, Q23 is turned on and D10 is cut off. Therefore, the voltages of both Zener diodes D11 and D12 are added; 13V is now applied to the fan motor through the MOT terminal. Thus, the fan motor speeds-up to cool the heat sink rapidly. Simultaneously, the H logic level at Q19 collector is sent to the Signal unit through the THP terminal to switch the transceiver from transmission to reception. This circuit is reset and transmission is re-enabled when the temperature drops below $65-70\,^{\circ}\text{C}$ (nominal). After reset, the fan continues to operate until the final heat sink temperature drops below about $45\,^{\circ}\text{C}$. (See Fig. 15.)

Fig. 15 Fan, temperature protection (Final amps)

Power supply cooling fan control circuit in the Power supply unit

This circuit monitors the power supply heat sink temperature through thermistor TH1. Its operation is similar to the Final unit fan control circuit, previously discussed. It turns the fan on when the power supply heat sink temperature reaches about 60 °C and turns off when the temperature drops below about 50 °C.

CW full break-in timing circuit in the Signal unit

Fig. 16 is the timing chart for CW full break-in and sendreceive switching in the SSB, FSK and TUNE modes. The TS-930S uses TV, RV, TR, TBK and ALC as timing signals for T-R switching. TV and RV are the power supply voltages for the send and receive systems. About 3ms of quiscent time is provided for both TV and RV at each send-receive switching transition. The operating state is passed to the PLL unit by the TR signal for frequency control during RIT or split frequency operation. TV goes "L" about 6ms after TBK goes "L". During this 6ms period, the TX RF power drops together with the ALC voltage. TB is the bias voltage for the send system and RB is that for the receive system. TB and TV are switched simultaneously. RB is on when TB is off, and vice versa. Fig. 17 shows the timing for CW semi-break-in and for CW keying after the standby switch has been placed to SEND. Note: Omitted signals (such as RV and TR) are the same as shown in Fig. 16.

CW FULL BRAKE IN

• ALC circuit in the Signal unit

For all modes, except CW full break-in, forward wave voltage VSF detected in the Filter unit is applied to the base of Q45 in the Signal unit. Q45 and Q44 form a differential amplifier. When VSF is applied, the collector voltage of Q44 rises and that of Q47 drops. The gate voltage of Q52 then drops, as do the base and emitter voltages of Q51. As a result, the ALC line voltage is dropped through D70 and Q51 to control transmitter power. The level at the drain of Q52 is applied to the ALC meter. VR11 is the 0 adjustment, and VR12 is the sensitivity adjustment. For full break-in operation, the TBK signal generated during keying is applied to active low pass filter Q50, where key clicks are removed. This filtered signal is used as the ALC signal and is fed to the ALC line. As previously shown, the ALC voltage not only controls transmission power, but is also used for waveform shaping during CW operation.

VSWR protection circuit in the Signal unit

Reflected wave voltage VSR is applied to the base of Q48 in the Signal unit. When the reflected power exceeds 25W (an SWR of about 3:1), Q48 is turned on and the voltage input to the ALC circuit is dropped to reduce transmission power.

• Final overcurrent protection circuit in the Signal unit Current flowing through the Final unit 28V line is detected across R14 (0.05 Ω). The voltage drop across R14 is amplified by IC4/4 and applied to Q49. When current exceeds approximately 15A, Q49 is turned on and the voltage input to the ALC circuit is dropped to reduce the transmission power.

ANTENNA TUNER

A block diagram of the antenna tuner is shown in Fig. 20. This antenna tuner covers all amateur bands from 3.5 through 29MHz. When the operating frequency is within a 500kHz band segment which includes an amateur band (except the 1.8MHz band), the automatic antenna tuner will operate if the AUTO-THRU switch is set to AUTO. When the operating frequency is at any other frequency, the tuner is automatically bypassed regardless of the AUTO-THRU switch position.

When the AUTO-THRU switch is set to AUTO, voltages proportional to the antenna line voltage and current are induced across the directional coupler terminals. The directional coupler is a toroidal core transformer having excellent characteristics in the 3.5 to 30.0MHz range.

Voltage proportional to the antenna line current is applied to Q30 pin 9, and voltage proportional to the antenna line voltage is applied to Q30 pin 13. Both voltage signals are

shaped by Q30 and applied to phase comparator Q29. The output level of Q29 changes according to the relationship between the phase of the antenna line current and voltage. This signal is applied to buffer Q28 pins 10 and 15. The levels at pins 12 and 13 change according to the input level, and these signals are applied to Q31 and Q32 (which control the motor drive circuit consisting of Q14 through Q19) so that motor M1 turns in either one direction or the other, according to the phase relationship, until the phase difference is minimized.

Voltages picked up by the directional coupler are also applied to Q39 pins 4 and 6 for comparison. When the voltage at pin 6 is higher than that at pin 4, the level at pin 1 is "H" and that at pin 2 is "L" (and vice versa). Motor M2 turns in either one direction or the other, according to these levels. The circuit is designed so that VC1 and VC2 (that is, M1 and M2) operate independently. However, since phase and voltage are not independent, both VC1 and VC2 operate as either phase or voltage varies.

When the input voltages to Q39 become equal, the level at pin 5 (or pin 7) is determined by the divider consisting of R100 and R104 (or R105 and R101) so it is lower than the corresponding input level; then output levels at both pins 1 and 2 go "L", the motor drive circuit turns off and the motor stops.

A current signal proportional to the SWR is derived by the SWR calculation circuit in the Signal unit, and is input to the Antenna tuner unit through the ISW terminal. This current signal is applied to Q40b pin 2 and converted to a voltage signal. The input level at Q39c pin 8 is set to the level equal to the output level of Q40b when the SWR is 1.2. Therefore, the output level at Q39c pin 14 is "H" when SWR is higher than 1.2. This "H" signal is applied to Q11 so that Q11, Q10 and Q34 are turned on and the motor drive circuits are enabled. When SWR becomes 1.2 or less, the level at Q39c pin 14 goes "L". Therefore, Q11, Q10 and Q34 turn off and the motor drive circuits are disabled.

Generally, the tuning motors should run at high speed to reduce the time required to tune the antenna. If this were done, however, inertia would cause the motor to overrun after the motor stops when the SWR becomes 1.2 or less. This would cause the SWR to again become greater than 1.2, and the motor to operate in reverse. This might repeat infinitely. On the other hand, it requires a longer time to tune the antenna if the motor speed is too slow. The motor control system employed in the AT-930 is as follows. Q41 forms a multivibrator and its output is applied to Q40a pin 6. A signal proportional to the SWR is applied to Q40a pin 5. The signal output by Q40 is a pulse whose width increases as the SWR becomes higher, or vice versa. This pulse signal is applied to Q38, then Q34, so that motor speed increases when the SWR is high and reduces when it is low.

The antenna tuner is provided with a protection circuit which disables the AUTO-THRU switch during transmission. When the AUTO-THRU switch is at THRU, D13 is on, D14 is off and Q36 is off. Q35 is on because a "H" is applied through D15. The "H" at the collector of Q36 is applied to Q8 through D9 and turnes Q8 on. Thus, Q7 is on and relay RL1 is actuated. When the AUTO-THRU switch is at AUTO, D12 is on, so D11 and Q35 are off. The collector level at Q35 is applied to Q36 through D10 so Q36 is on. Therefore, Q36 collector level is "L" and Q8 is off. Thus, Q7 and RL1 are off. During transmission, RXB is "L" and both D12 and D13 are turned off, so the AUTO-THRU switch is disconnected from Q35 and Q36. Therefore, the AUTO-THRU switch has no affect.

The BAND data signals for the 3.5MHz to 29MHz Amateur bands are sent from the Digital unit through terminals AT1 to AT6. (See Table 6.) The AT1 signal is used for automatic antenna tuner control; its level is "H" when the operating frequency is within a 500 kHz Amateur band segment. At such time, Q9 is on and D8 is off. This allows Q8 to be controlled through D9. When the level is "L", Q9 is off and D8 is on. Therefore, the level at the base of Q8 is maintained at "H" through R17. (Q8 is always on; that is, the tuner is in the THRU state.)

The matching circuit used is a "T" configuration when the operating frequency is between 3.5MHz and 14MHz, and a π configuration when the operating frequency is 18MHz or above. Switching between the two is performed by relay RL8. When the motors are operating, the green LED ingicator on the front panel lights. This indicator goes off when the motors stop at best match.

Guaranteed attenuation (0.1 – 1 MHz)	60dB or more
Spurious (600-700kHz)	40dB or more
Ripple	2dB or less
Loss	6dB or less
Input and output impedance	2kΩ

SSB ceramic filter (L72-0334-05) (Signal unit CF1)

Item	Rating
Nominal center frequency	8830.0kHz
Center frequency deviation	Within ±70Hz at 6dB (25°C)
Pass bandwidth	± 250Hz or more at 6dB
Attenuation bandwidth	±900Hz or less at 60dB
Guaranteed attenuation	80dB or more within ±2kHz-±1MHz
Ripple	2dB or less
Loss	Within 5dB ± 2dB
Input and output impedance	600Ω / 15pF

CW crystal filter YK-88C-1 (L71-0236-05) Option

Item	Rating
Nominal center frequency	8830.0kHz
Center frequency deviation	Within ±250Hz at 6dB
Pass bandwidth	±3.0kHz or more at 6dB
Attenuation bandwidth	±6kHz or less at 60dB ±10kHz or less at 80dB
Ripple	2dB or less
Loss	Within 3dB ± 2dB
Guaranteed attenuation	80dB or more within ± 10kHz-±1MHz
Input and output impedance	600Ω / 15pF

AM crystal filter YK-88A-1 (L71-0237-05) Option

Item	Rating		
Center frequency	455kHz		
, viation	Within 50Hz at 6dB		
A SHEETING TO BE A SECOND			
Charles and Charle			
	80dB or more within		
Guaranteed attenuation	100Hz - 454.4kHz		
Guaranteeu attenuation	80dB or more within		
	455.6kHz - 2MHz		
Input and output impedance	2kΩ ± 5% / 15pF ± 5%		

CW crystal filter YG-455C-1 (L72-0238-05) Option

Item	Rating
Center frequency	455kHz
Center frequency deviation	Within 50Hz at 6dB
Pass bandwidth	± 125Hz or more at 6dB
Attenuation bandwidth	±250Hz or less at 60dB
Ripple	2dB or less
Loss	6dB or less
Guaranteed attenuation	80dB or more within 100Hz – 454.6kHz 80dB or more within 455.4kHz – 2MHz
Input and output impedance	2kΩ ± 5% / 15pF ± 5%

Item	Symbol	Rating
Gate-Drain voltage	VCDO	-25V
Gate-Source voltage	V _{GSO}	-25V
Continuous Drain current	I _D	100mA
Continuous Gate current	IG	10mA
Power dissipation	Pch	500mW
Channel temperature	Tch	120°C
Storage temperature	Tstg	-50~+120°C

Note:

Soldering procedure for the chip capacitor

Tools and materials

Soldering iron

1/8"-3/32" wide wedge tip

Solder (Silver solder or low temperature solder)

Soft jaw tweezers

Hot plate or drier

- Soldering procedure
 - 1) Pre-heat the surface of chip capacitor up to around 150°C with the hot plate or drier.
 - 2) Apply solder to the tip of soldering iron.
 - Hold and place the chip capacitor on the installation place with the tweezers.
 - 4) Solder one end of the chip capacitor using the tip of soldering iron.
 - 5) Solder the other end similarly.
- Caution
 - Do not use too much solder. Use only enough solder to secure the component.

2) Length of soldering time:

In case of silver solder: Within 6 - 8 sec.

In case of low temperature solder: Within 3 - 4 sec.

 Keep the temperature of tip of soldering iron below 280°C.

Note: If you damage the silver plating on the ends of the capacitors, they should be discarded as they are no longer capable of performing correctly.

Use care when soldering. Liberal use of additional flux will ease the task of soldering.

DISASSEMBLY

DISASSEMBLY

DISASSEMBLY

Disassembly and cautions for rear panel

- (1) Take care not to damage terminals ANT and GND on the rear panel since they are soldered or screwed to the PC board.
- (2) When repairing the final section, remove the upper and lower cases, then the final heatsink and shield case for the Filter unit. (When repairing the Filter unit, remove the above parts, too.)

Disassembly and cautions for internal mechanism

- (1) Cautions on replacement of transformer

 Tighten the beyagon socket head holts to a
 - Tighten the hexagon socket head bolts to a torque of 20kg-cm. Check the transformer for shock, looseness, and correspondence.
- (2) When repairing the Signal unit under the chassis, take much care.
 - To remove the PC board from the chassis, remove 19 screws.
 - The weight of PC board and radiator plate is about 1kg in total.
 - However, the optional filter can be installed easily without removing the Signal PC board.
- (3) Removing mounting hardware for the electrolytic capacitor
 - The mounting hardware for electric capacitor can be removed by removing two screws from one side of the mounting hardware and sliding it toward the screws (to left side when viewed from the front panel).
- (4) The speaker is installed to the mounting hardware on the chassis, different from the models in the past.

62

Disassembly for front panel

- (1) The front panel may be tilted for servicing by removing the 2 flat head screws at the top sides of the panel, and loosening the 2 round head screws at the bottom. Use caution as the panel is heavy and may fall forward.
- (2) When replacing the name plate on the display window for display tube and meter,1st remove the meter. Push the name plate from rear with a thin screw driver through the square hole on the panel. When replacing the front glass, remove the name plate and two flat screws (M2 x 6). (The front glass grille can be removed at the same time.)
- (3) When removing the display tube from the mounting bracket, insert a thin screw driver, etc. into the bracket at both sides. Remove the display tube with the screw driver form the projection of the mounting hardware for display tube.
- (4) Removing main knob
 - Slip the outside rubber ring from the knob. The allen set screw can now be loosened and the knob removed.
- (5) Removing band switch assembly
 - Remove the six screws securing the PC board. Then, remove push knobs (1.5 3.5), cushions, and the four round screws which secure the escutcheon to the front panel.

ADJUSTMENT

REQUIRED TEST EQUIPMENT

DC Voltmeter (DC V.M)

1) Input resistance: More than $1M\Omega$ 2) Voltage range: 1.5 to 1000 V AC/DC

NOTE: A high-precision multimeter may be used. However, accurate readings can not be obtained for high-impedance circuits.

2. DC Ammeter

1) Current range: 100mA, 1.5A, 15A, High-precision ammeter may be used.

3. RF VTVM (RF V.M)

1) Input impedance : $1M\Omega$ and less than 3pF, min.

2) Voltage range: 10 mV to 300 V

3) Frequency range: 10 kHz to 100 MHz or greater

4. AF Voltmeter (AF V.M)

1) Frequency range: 50 Hz to 10 kHz 2) Input resistance : $1 M\Omega$ or greater

3) Voltage range: 10 mV to 30 V

AF Generator (AG)

1) Frequency range: 200 Hz to 5 kHz

2) Output: 1 mV or less to 1 V, low distortion

6. AF Dummy Load

1) Impedance : 8Ω

2) Dissipation: 3W or greater

7. Oscilloscope (Dual trace)

Requires high sensitivity, and external synchronization capability.

Sweep Generator

1) Center frequency: 50 kHz to 90 MHz

2) Frequency deviation: Maximum±35MHz

3) Output voltage: 0.1 V or greater

4) Sweep rate: At least 0.5 sec/cm

9. Standard Signal Generator (SSG)

1) Frequency range: 50 kHz to 50 MHz

2) Output : $-20 dB/0.1 \mu V$ to 120 dB/1 V

3) Output impedance : 50Ω

4) AM and FM modulation can be possible.

NOTE: Generator must be frequency stable.

10. Frequency Counter (f. counter)

1) Minimum input voltage: 50 mV

2) Frequency range: 50 MHz or greater

3)

11. Noise Generator

Must generate ignition-like noise containing harmonics beyond 30 MHz.

12. RF Dummy Load

1) Impedance : 150Ω

Dissipation: 150W or greater

13. Power Meter

1) Impedance : 50Ω

2) Dissipation: 150W continuous or greater

Frequency limit: 60MHz or greater

14. Spectrum Analyzer

1) Frequency range: 100kHz to 110MHz or greater

2) Bandwidth: 1 kHz to 3MHz

15. Detector

1) For adjustment of TX BPF

For adjustment of PLL/VCO BPF

16. Directional Coupler

17. Monitor Receiver

R-1000 class

18. Microphone

MIC terminals (View from front panel side)

PREPARATION

Description

SCHEMATIC DIAGRAM

TS-930S

SP-930

PACKING

AT-930

AT-930 SPECIFICATIONS

Frequency range: 3.5–29.7 MHz, all amateur bands Band Selection: Automatic, by band information

from the transceiver.

Input impedance: 50 ohms, unbalanced
Output impedance: 20–150 ohms, unbalanced
Insertion loss: Less than 1 dB at 29.7 MHz

(at best match)

Max. input power: 150W

Motor stop SWR: Less than 1.2

PARTS LIST

N : New parts

Parts No.	Re- marks	Description	Ref. No.

SUBJECT:

Digital Unit through-plated hole defects and their symptoms

CONTENTS:

The unit shows symptoms as listed below, when any of the 56 Digital Unit through-plated holes are open. These examples were compiled by Mr. Negishi of the Kanto service center. Make full use of the Material as a technical reference for repair.

Through-hole No.	Symptom
1	(GND)
1	(OID)
2	(GND)
3	Transmit mode not entered.
4	N/C
5	No display. However, pressing the BAND switch operates the BAND changeover relay.
6	Transmit mode not entered.
7	N/C
8	RIT operates in transmit mode.
9	Continuous tone and no display.
10	RIT operates in transmit mode.
11	(GND)
12	(GND)
13	Continuous sound. All indications are displayed.
14	(GND)

16 & 17No displa	ay, display disappears when main dial is turned, or displant nothing is displayed). Turning the main dial generates an abnormal sound. frequency is approached.	• 11		·	ve

16 & 17No display,	display disappears when main dial is turned, or display appears when main dial is turned (when nothing is displayed).
18	Turning the main dial generates an abnormal sound. The abnormal sound increases as the receive frequency is approached.
19	No display. However, 80.888.8 .88 is displayed when connector 9 is removed.
20	No display or 54.444.4 is displayed.
21	36.222.2 or 14.444.4 is displayed.
22	RIT-1.1 kHz is displayed when an odd numbered frequency is displayed.
23	Only the 'g' segment of the display lights; "-"
24	
25	
26	No display or only segments "egf" light. "1-"
27 & 28	The main dial and UP and DOWN switches do not operate.
29	
30	Only segments "g, DP" light.
31	Many analog pointers light. The brightness of the pointers varies widely.
32	All 'g' segments light. " "
33	The "DP" segment remains continuously it.
34	Analog values from 0 to 700 are displayed, but values from 700 to 1000 are not.
35	Segments "b,g" only are not displayed. Some of the analog pointers do not light.
36	
37	No display because UL.
